JOB BOARD_

< CODE YOUR WAY TO YOUR NEXT JOB />

JOB BOARD

Professional opportunities are out there — but finding the right one can be a challenge.
Job and internship offers are scattered across many platforms, with similar or duplicate listings making the search time-consuming.

In this project, you'll build a solution that collects offers, and helps users find relevant opportunities.

Along the way, you'll apply the technical and methodological skills you've developed to a project that connects directly to your own future: your job search.

{EPITECH}

Overview

This project aims to deliver the following:

- ✓ a database to store job advertisements ;
- ✓ a webpage (*front end*) using Javascript technologies to display an online job advertisements board as well as an administration page for the admin user ;
- ✓ an API (*back end*):
  - to allow users to apply for jobs ;
  - to manage the DB (only for admin user) with **CRUD** operations.

All your work must be tested locally.

Database

Your solution relies on an SQL database storing job advertisements.
It must contain at least:

- ✓ a table to store advertisements ;
- ✓ a table to store companies ;
- ✓ a table to store people (in charge of or applying to an advertisement) ;
- ✓ a table to keep information about a job application (emails sent, people/ad concerned, etc.).

The database fields must be consistent with the information displayed on the web pages.

You can add as many relevant tables/fields as you want.

Fill in the database using your backend.

API

Your back end exposes an API providing CRUD operations (Create, Read, Update, Delete) on the database tables.
All the dynamic data displayed by the front end must be retrieved through this API.

Attention must be paid to using the appropriate HTTP verbs and the RESTful API routing rules.

You can use the language you feel comfortable with. Here are some candidates: Python (with Flask or FastAPI), NodeJS (with Express.js), PHP (with Laravel or Lumen), ...

Job board

The main page of your application is an HTML/CSS page listing job advertisements.
Each ad displays at least a title, a short description, a ”learn more” button and an ”Apply” button.

Learn more

The ”learn more” button displays all the available information about the ad (full description, wages, place, working time, ...), fetched dynamically from the API, without reloading the page.
No popup.

Apply

The ”Apply” button opens a form allowing the user to:

- ✓ enter information about themselves (name, email, phone, ...) ;
- ✓ send a message to the owner of the ad (you).

Each application must be saved in the database.

Authentication

Users can sign in to the application.
Once identified, a user does not have to fill in their personal information to apply to a job.

You need a **connection** page and another one to create/modify an account.

A successful connection redirects an admin user to the administration page, and any other user to the job board.

Administration

An HTML/CSS page allows the admin to monitor the database. From this page, the admin can list all the records of your tables, create new records, and update or delete the existing ones.

This page can be accessed only by an admin.

Think about pagination when displaying a big list of database records.

The layout is up to you. Make it simple and user-friendly.

Design

The design of your pages is up to you, but it must be polished: take care of your style sheets and the overall user experience.

Focus first on features, then refine the design once everything works.

Delivery

Your delivery must include a **README** explaining how to install, configure and run your project, and describing its main components (database schema, API routes, pages).

v 4.0.0
